

The patented spherical jar

- The lifetime yield of a bee is 1 teaspoon of honey. Conventional honey glasses cannot be completely emptied with a teaspoon. Especially the small jars for breakfast or room service are not suited for a spoon. Customers may fill to jar with hot tea. That technique will empty the glass but destroy the heat-sensitive components of honey. The life-span honey production by a single bee is a teaspoon of honey. Large amounts of honey are wasted daily and world-wide because jars and spoons do not fit together.
- Our jar has been designed around a teaspoon. We hope so to reduce honey waste. It is patented, No 018088496..
- The lid is biodegradable, developed by a German start-up company.
- No matter how you tilt the jar, it will always roll back to its upright position. We hope so to reduce the risk of the glass of rolling from breakfast tables.
